

TWIN DUCKBILL VALVE ASSEMBLY

This invention relates generally to the field of duckbill valves, and more specifically concerns a new duckbill valve arrangement.

5 Duckbill valves are in general well known. A duckbill valve includes a slit at a front (upper) end thereof which under positive differential pressure opens to permit exit of fluid therethrough. Otherwise, the slit is closed and resistant to backflow under negative pressure. Various shapes and sizes of duckbill valves are used for particular applications. One example is the use of a duckbill valve in fluid-dispensing toothbrushes.

10 However, the currently available duckbill valves used in toothbrushes have been known to fall out of the toothbrush bristle plate, or can be easily pulled out from the bristle plate in which they are mounted. Further, there is typically no easy, reliable way to properly orient the duckbill valve in the bristle plates using automated manufacturing equipment. Hence, the duckbill valve may end up with the slit at various orientations in the bristle plate.

15 In addition, conventional duckbill valves can become clogged, or the exiting fluid may not cover the desired area because of limitations in existing duckbill valve configurations. Further, particularly for toothbrushes, there may be a need to deliver more than one fluid, which results in fluid path complexity to the duckbill valve.

20 It would be desirable to have a duckbill valve which overcomes one or more of the disadvantages discussed above.

Accordingly, the present invention is a duckbill valve assembly, comprising:

At least two duckbill valve members; and a flange member which extends between and joins the duckbill valve members in a particular orientation.

25 Figure 1 is an exploded view showing the duckbill valve of the present invention in a stem/brushhead portion of a toothbrush.

Figure 2 is a perspective view of the duckbill valve shown in Figure 1.

Figure 3 is a front view of a toothbrush stem/brushhead with the duckbill valve of Figures 1 and 2.

30 Figure 4 is a cross-sectional view of a toothbrush brushhead with the duckbill valve of Figures 1 and 2.

Referring now to Figure 2, the twin duckbill valve assembly of the present invention, shown generally at 10, includes two individual duckbill valve members 12 and

14 joined by a flange 16 at the respective bases thereof. Duckbill valve members 12 and 14 are similar to conventional duckbill valves in that they have a circular lower portion 18 and a tapered upper portion 20 with a rectangular upper surface 21. Each duckbill valve member 12 and 14 is hollow, with an open base (lower end) to receive fluid and a slit 22 in
5 upper surface 21 which extends for most of the length of upper surface 21, through which fluid exits the valve. The duckbill valve members 12 and 14 are made from a flexible material, such as rubber.

Under positive differential pressure, slit 22 opens to allow the free flow of fluid through the valve. Under negative pressure, backflow through the valve is prevented
10 because the slit 22 remains firmly closed. Again, the basic structure of a duckbill valve is well known; a wide variety of duckbill valve sizes and configurations are available from various manufactures for different applications.

In applicant's invention, flange 16 joins the base of the two duckbill valve members, thereby creating a unitary article and maintaining the separate valve members in
15 a fixed spatial relationship.

In the embodiment shown, flange 16 is also made of flexible material and is approximately 0.5 mm thick. While flange 16 can have various configurations, the configuration shown in Figure 2, which includes two straight parallel longitudinal sides 28 and 30, with curved end portions 32 and 34 joining the longitudinal sides and extending
20 slightly beyond the edge of the duckbill valve members, is preferred for ease of manufacturing. In the embodiment shown, flange 16 is 13.8 mm long, approximately 4.2 mm wide, with the centerlines of the two duckbill members being separated by 10.5 mm. These dimensions can be varied for different applications.

Figure 1 shows an exploded view of the twin duckbill valve assembly 10 in a
25 toothbrush application. Figures 3 and 4 show views of the assembled combination.

Duckbill valve assembly 10 is inserted into a cavity 42 in bristle plate 44, with the two individual duckbill valve members 12 and 14 extending through spaced openings in a remaining thickness portion 48 of the bristle plate, such that they extend into the field of bristles 50 mounted on the bristle plate 44. A holding member 55 is then positioned over
30 the duckbill valve assembly 10 in cavity 42, holding the assembly in place therein against the remaining thickness portion 48 of the bristle plate. The inserted holding member is configured to define cavities 57 or channels in the bristle plate which receive fluid from a

reservoir through stem portion 58. The open bases of the duckbill members are in fluid communication with the cavity in the bristle plate through openings 52 and 54 in flange 16. This arrangement allows fluid under positive pressure to flow into the individual duckbill valve members 12 and 14 and out through the slitted upper ends thereof into
5 bristle field 50.

While the arrangement shown includes two individual duckbill valve members which are oriented such that their slits 22-22 are parallel to each other laterally across flange 16, the two duckbill valve members could be oriented so that the slits are in a single line along the toothbrush (in a single vertical plane).

10 Furthermore, it should be understood that there may be more than two duckbill valve members in a particular assembly. Still further, the individual duckbill valve members, respectively, could have different sizes and/or shapes, different from each other, to accommodate two different liquids. If the two duckbill valve members are connected to the same fluid path, however, it is advantageous for the two duckbill valve members to be
15 of the same size, shape and orientation. Still further, in a toothbrush application, it is advantageous for the duckbill valve members to be separated by a distance, to accommodate bristles in the bristle field therebetween, such as shown particularly in Figure 1.

There are several advantages to the multiple duckbill valve assembly of the present
20 invention. First, it permits an easy automatic assembly with proper duckbill orientation, as the duckbill valve assembly can only fit into the bristle plate in one orientation. Still further, it is very difficult to pull the duckbill out from the bristle plate, since the flange 16 abuts the inner surface of the remaining thickness portion 48 of the bristle plate. Also, as indicated above, the present duckbill assembly structure can accommodate two separate
25 fluid paths through the toothbrush stem for two different fluids. Hence, the multiple duckbill valve assembly of the present invention overcomes disadvantages of a single duckbill assembly, but also has additional advantages thereover.

Although a preferred embodiment of the invention has been disclosed for purposes of illustration it should be understood that various changes, modifications and substitutions
30 may be incorporated in the embodiment without departed from the spirit of the invention which is defined by the claims as follows:
